Community Detection Methods for the Generalized Random Dot Product Graph Model Dissertation Proposal

John Koo

June 2021

Community Detection for Networks

How can we cluster the nodes of a network?

Statistical inference (parametric approach):

- 1. Define a generative model $G \mid z_1,...,z_n, \vec{\theta} \sim P(\vec{z},\vec{\theta})$.
- 2. Develop a method for obtaining estimators $f(G) = \hat{z}_1,...,\hat{z}_n$.
- Identify asymptotic properties of estimators and prove consistency.

Overview

- 1. Probability Models for Networks
 - Block Models and Community Structure
 - (Generalized) Random Dot Product Graphs
 - Connecting Block Models to the (G)RDPG
- 2. Popularity Adjusted Block Model
 - Connecting the PABM to the GRDPG
 - Subspace Clustering for Community Detection
 - Orthogonal Spectral Clustering
- Community Detection for the (G)RDPG
 - Manifold Clustering
 - Manfolds as (G)RDPG Latent Configurations

Probability Models for Networks

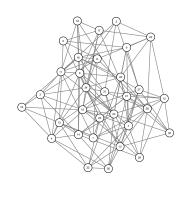

Bernoulli Graphs

Let G=(V,E) be an undirected and unweighted graph with |V|=n. G is described by adjacency matrix A such that $A_{ij}= \begin{cases} 1 & \exists \text{ edge between } i \text{ and } j \\ 0 & \text{else} \end{cases}$

 $A_{ji} = A_{ij}$ and $A_{ii} = 0 \ \forall i, j \in [n]$. $A \sim BernoulliGraph(P)$ iff:

- 1. $P \in [0,1]^{n \times n}$ describes edge probabilities between pairs of vertices.
- 2. $A_{ij} \stackrel{ind}{\sim} Bernoulli(P_{ij})$ for each i < j.

Example: If G is an Erdos-Renyi graph, then $P_{ij}=\theta$.

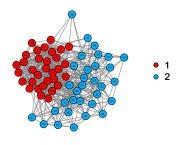

Block Models

Suppose each vertex $v_1,...,v_n$ has hidden labels $z_1,...,z_n\in [K]$, and each P_{ij} depends on labels z_i and z_j .

Example 1: Stochastic Block Model with two communities

Then $A \sim BernoulliGraph(P)$ is a block model.

- $z_1, ..., z_n \in \{1, 2\}$ • $P_{ij} = \begin{cases} p & z_i = z_j = 1\\ q & z_i = z_j = 2\\ r & z_i \neq z_j \end{cases}$
- To make this an assortative SBM, set $pq>r^2$
- In this example, p=1/2, q=1/4, and r=1/8.

Block Models

Erdos-Renyi Model (1959)

- $P_{ij} = \theta$
- Not a block model

Stochastic Block Model (Lorrain and White, 1971)

- $P_{ij} = \theta_{z_i z_j}$
- K(K+1)/2 parameters θ_{kl}

Degree Corrected Block Model (Karrer and Newman, 2011)

- $P_{ij} = \theta_{z_i z_j} \omega_i \omega_j$
- K(K+1)/2 + n parameters θ_{kl} , ω_i

Popularity Adjusted Block Model (Sengupta and Chen, 2017)

- $P_{ij} = \lambda_{iz_j}\lambda_{jz_i}$
- Kn parameters λ_{ik}

Hierarchy of Block Models

PABM \rightarrow DCBM: $\lambda_{ik} = \sqrt{\theta_{z_i k}} \omega_i$

 $DCBM \rightarrow SBM: \omega_i = 1$

 $\mathsf{SBM} \to \mathsf{Erdos} ext{-Renyi: } \theta_{kl} = \theta$

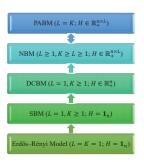

Figure 2: The hierarchy of block models

Majid Noroozi and Marianna Pensky, 2021

(Generalized) Random Dot Product Graph Model

Random Dot Product Graph $A \sim RDPG(X)$ (Young and Scheinerman, 2007)

- Latent vectors $x_1,...,x_n \in \mathbb{R}^d$ such that $x_i^{\top}x_j \in [0,1]$
- $A \sim BernoulliGraph(XX^{\top})$ where $X = \begin{bmatrix} x_1 & \cdots & x_n \end{bmatrix}^{\top}$

Generalized Random Dot Product Graph $A \sim GRDPG_{p,q}(X)$ (Rubin-Delanchy, Cape, Tang, Priebe, 2020)

- Latent vectors $x_1,...,x_n \in \mathbb{R}^{p+q}$ such that $x_i^{\top}I_{p,q}x_j \in [0,1]$ and $I_{p,q} = blockdiag(I_p,-I_q)$
- $A \sim BernoulliGraph(XI_{p,q}X^{\top})$ where $X = \begin{bmatrix} x_1 & \cdots & x_n \end{bmatrix}^{\top}$

If latent vectors $X_1,...,X_n \stackrel{iid}{\sim} F$, then we write $(A,X) \sim RDPG(F,n)$ or $(A,X) \sim GRDPG_{p,q}(F,n)$.

ç

(Generalized) Random Dot Product Graph Model

Recovery/Estimation

Want to estimate X from A, or alternatively, interpoint distances, inner products, or angles.

Adjacency Spectral Embedding

To embed in \mathbb{R}^d ,

- 1. Compute $A \approx \hat{V} \hat{\Lambda} \hat{V}^{\top}$ where $\hat{\Lambda} \in \mathbb{R}^{d \times d}$ and $\hat{V} \in \mathbb{R}^{n \times d}$. For RDPG, use d greatest eigenvalues; for GRDPG, use p most positive and q most negative eigenvalues.
- 2. For RDPG, let $\hat{X}=\hat{V}\hat{\Lambda}^{1/2}$; for GRDPG, let $\hat{X}=\hat{V}|\hat{\Lambda}|^{1/2}$.

RDPG: $\max_{i} \|\hat{X}_{i} - W_{n}X_{i}\| \stackrel{a.s.}{\to} 0$ (Athreya et al., 2018) GRDPG: $\max_{i} \|\hat{X}_{i} - Q_{n}X_{i}\| \stackrel{a.s.}{\to} 0$ (Rubin-Delanchy et al., 2020)

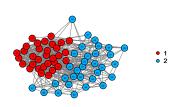

Connecting Block Models to the (G)RDPG Model

All Bernoulli Graphs are RDPG (if P is positive semidefinite) or GRDPG.

Example 1 (cont'd): Assortative SBM $(pq > r^2)$ with K = 2

$$P_{ij} = \begin{cases} p & z_i = z_j = 1\\ q & z_i = z_j = 2\\ r & z_i \neq z_j \end{cases}$$

$$P = \begin{bmatrix} P^{(11)} & P^{(12)} \\ P^{(21)} & P^{(22)} \end{bmatrix} = XX^{\top}$$

$$X = \begin{bmatrix} \sqrt{p} & 0\\ \vdots & \vdots\\ \sqrt{p} & 0\\ \sqrt{r^2/p} & \sqrt{q - r^2/p}\\ \vdots & \vdots\\ \sqrt{r^2/p} & \sqrt{q - r^2/p} \end{bmatrix}$$

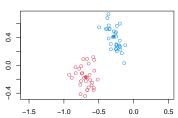

Connecting Block Models to the (G)RDPG Model

Example 1 (cont'd)

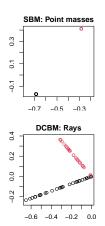

If we want to perform community detection,

- 1. Note that $A \sim BernoulliGraph(XX^{\top})$ is a RDPG
- 2. Compute the ASE $A \approx \hat{X}\hat{X}^{\top}$ $\hat{X} = \hat{V}\hat{\Lambda}^{1/2}$
- 3. Apply clustering algorithm (e.g., K-means) to \hat{X}

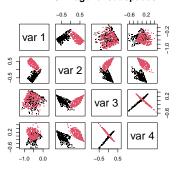

ASE of the adjacency matrix drawn from SBM

Connecting Block Models to the (G)RDPG Model

PABM: Orthogonal subspaces

Popularity Adjusted Block Model

Popularity Adjusted Block Model

Def Popularity Adjusted Block Model (Sengupta and Chen, 2017):

Let each vertex $i \in [n]$ have K popularity parameters $\lambda_{i1},...,\lambda_{iK} \in [0,1]$. Then $A \sim PABM(P)$ if each $P_{ij} = \lambda_{iz_j}\lambda_{jz_i}$.

Lemma (Noroozi, Rimal, and Pensky, 2020):

A is sampled from a PABM if P can be described as:

- 1. Let each $P^{(kl)}$ denote the $n_k \times n_l$ matrix of edge probabilities between communities k and l.
- 2. Organize popularity parameters as vectors $\lambda^{(kl)} \in \mathbb{R}^{n_k}$ such that $\lambda_i^{(kl)} = \lambda_{k_i l}$ is the popularity parameter of the i^{th} vertex of community k towards community l.
- 3. Each block can be decomposed as $P^{(kl)} = \lambda^{(kl)} (\lambda^{(lk)})^{\top}$.

Notation: $A \sim PABM(\{\lambda^{(kl)}\}_K)$.

Connecting the PABM to the GRDPG (K = 2)

Theorem (KTT): Given popularity vectors $\{\lambda^{(kl)}\}_2$, we can define block diagonal $X \in \mathbb{R}^{n \times 4}$ and $U \in \mathbb{O}(4)$ such that $A \sim PABM(\lambda_2^{(kl)})$ is equivalent to $A \sim GRDPG(XU)$.

Proof: Decompose P as follows

$$X = \begin{bmatrix} \lambda^{(11)} & \lambda^{(12)} & 0 & 0\\ 0 & 0 & \lambda^{(21)} & \lambda^{(22)} \end{bmatrix}$$
$$U = \begin{bmatrix} 1 & 0 & 0 & 0\\ 0 & 0 & 1/\sqrt{2} & 1/\sqrt{2}\\ 0 & 0 & 1/\sqrt{2} & -1/\sqrt{2} \end{bmatrix}$$

$$P = (XU)I_{3,1}(XU)^{\top} = \begin{bmatrix} \lambda^{(11)}(\lambda^{(11)})^{\top} & \lambda^{(12)}(\lambda^{(21)})^{\top} \\ \lambda^{(21)}(\lambda^{(12)})^{\top} & \lambda^{(22)}(\lambda^{(22)})^{\top} \end{bmatrix}$$

Connecting the PABM to the GRDPG

Theorem (KTT): $A \sim PABM(\{\lambda^{(kl)}\}_K)$ is equivalent to $A \sim GRDPG_{p,q}(XU)$ with

- p = K(K+1)/2, q = K(K-1)/2
- $U \in \mathbb{O}(K^2)$
- $X \in \mathbb{R}^{n \times K^2}$ is block diagonal and composed of $\{\lambda^{(kl)}\}_K$ with each block corresponding to a community \implies if x_i^\top and x_j^\top are two rows of XU corresponding to different communities, then $x_i^\top x_j = 0$.

Remark (non-uniqueness of the latent configuration): If $A \sim GRDPG_{p,q}(X)$, then $A \sim GRDPG_{p,q}(XQ)$ for any Q in the indefinite orthogonal group with signature p,q.

Corollary: Since X is block diagonal by community and U is orthogonal, each community corresponds to a subspace in \mathbb{R}^{K^2} .

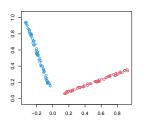

Subspace property holds even with linear transformation $Q\in \mathbb{O}(p,q).$

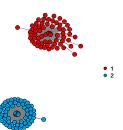

Sparse Subspace Clustering algorithm:

- 1. Solve n optimization problems $c_i = \arg\min_c \|c\|_1$ subject to $x_i = Xc$ and $c_i^{(i)} = 0$.
- 2. Compile solutions $C = \begin{bmatrix} c_1 & \cdots & c_n \end{bmatrix}$.
- 3. Construct affinity matrix $B = |C| + |C^{\top}|$.

Step (1) of SSC typically performed via LASSO: $c_i = \arg\min \frac{1}{2} \|x_i - X_{-i}c\|_2^2 + \lambda \|c\|_1$

If X obeys the Subspace Detection Property, then B is sparse such that $B_{ij} = 0$ if x_i and x_j belong to different subspaces

Noroozi et al. observed that the rank of P is K^2 and the columns of P belonging to each community has rank K to justify SSC for the PABM.

$$c_i = \arg\min_{c} \|c\|_1$$
 subject to $A_{\cdot,i} = Ac$ and $c^{(i)} = 0$

They were able to show that this obeys SDP if we replace A with P. GRDPG-based approach: Apply SSC to the ASE of A.

$$c_i = \arg\min_c \|c\|_1$$
 subject to $\hat{x}_i = \hat{X}c$ and $c^{(i)} = 0$
$$A \approx \hat{X}I_{p,q}\hat{X}^{\top}$$

Theorem (Wang and Xu, 2016): If data matrix X consists of points lying close to low-dimensional subspaces such that:

- 1. Each point's distance to its subspace is sufficiently small.
- 2. The points corresponding to each subspace cover a sufficient amount of that subspace.
- The cosine of the angles between pairs of subspaces is sufficiently small.

Then X obeys SDP.

Theorem (KTT): If $P = V\Lambda V^{\top}$ and $B = nVV^{\top}$, then $B_{ij} = 0$ $\forall i, j$ in different communities.

Theorem (KTT):

Let

- P_n describe the edge probability matrix of the PABM with n vertices, and $A_n \sim BernoulliGraph(P_n)$.
- \hat{V}_n be the matrix of eigenvectors of A_n corresponding to the K(K+1)/2 most positive and K(K-1)/2 most negative eigenvalues.

Then

• $\exists \lambda>0$ and $N<\infty$ such that when n>N, $\sqrt{n}\hat{V}_n$ obeys the Subspace Detection Property with probability 1.

Remarks:

- For large n, we can identify λ for SDP (Wang and Xu, 2016).
- SDP does not guarantee community detection.

Orthogonal Spectral Clustering

Theorem (KTT): If $P = V\Lambda V^{\top}$ and $B = nVV^{\top}$, then $B_{ij} = 0$ $\forall i, j$ in different communities.

Orthogonal Spectral Clustering algorithm:

- 1. Let V be the eigenvectors of A corresponding to the K(K+1)/2 most positive and K(K-1)/2 most negative eigenvalues.
- 2. Compute $B = |nVV^{\top}|$ applying $|\cdot|$ entry-wise.
- 3. Construct graph G using B as its similarity matrix.
- 4. Partition G into K disconnected subgraphs.

Theorem (KTT): Let \hat{B}_n with entries $\hat{B}_n^{(ij)}$ be the affinity matrix from OSC. Then \forall pairs (i,j) belonging to different communities and sparsity factor satisfying $n\rho_n=\omega\{(\log n)^{4c}\}$,

$$\max_{i,j} \hat{B}^{(ij)} = O_P\left(\frac{(\log n)^c}{\sqrt{n\rho_n}}\right)$$

General Community Detection for the (G)RDPG

Generative Model

Let $(A, X) \sim RDPG(F, n)$ such that

- 1. Define functions $f_1, ..., f_K$ such that $f_k : [0,1]^r \mapsto \mathbb{R}^d$ and $f_k(t) \neq f_l(t) \ \forall k, l \in [K].$
- 2. Sample labels $Z_1, ..., Z_n \stackrel{iid}{\sim} Categorical(\pi_1, ..., \pi_K)$.
- 3. Sample $T_1,...,T_n \stackrel{iid}{\sim} D$ with support $[0,1]^r$.
- 4. Set latent positions $X_i = f_{Z_i}(T_i)$ and $X = \begin{bmatrix} X_1 & \cdots & X_n \end{bmatrix}^{\top}$.
- 5. $A \sim BernoulliGraph(XX^{\top})$

Community Detection

Athreya et al. and Rubin-Delanchy et al.: we can approximate properties of the latent configurations via ASE.

General community detection method: Given A, K, and d (or p and q),

- 1. Use ASE to approximate the latent configuration.
- 2. Use the appropriate clustering algorithm for the form of the latent configuration (manifolds).

Parallel Segments

Example: Let $U_1,...,U_{n_1},U_{n_1+1},...,U_n \overset{iid}{\sim} Uniform(0,\cos\frac{\pi}{2}a)$, $f_1(t)=(t,0)$, and $f_2(t)=(t,a)$. $X_i=f_1(U_i)$ for $i\leq n_1$ and $X_j=f_2(U_j)$ for $n_1+1\leq j\leq n$. If we observe $X_1,...,X_{n_1},X_{n_1+1},...,X_n$, what approach will allow us to group the observations by segment?

 $\forall a \in (0,1), \ \delta \in (0,1), \ \text{and} \ K \geq 2, \ \exists N(a,\delta,K) < \infty \ \text{such that}$ when $\min_k n_k \geq N$, with probability at least $1-\delta$,

- 1. Single linkage clustering will produce perfect community detection.
- 2. Any ϵ -neighborhood graph with $\epsilon \leq a$ will consist of at least K disjoint subgraphs such that no subgraph contains members of two different communities.

Noisy Parallel Segments and One-Dimensional Manifolds

Example: Starting with the parallel segments as before, suppose instead of observing $X_1,...,X_n$, we have noisy observations $X_1+\xi_1,...,X_n+\xi_n$ such that $\max_i \|\xi_i\|=\xi \leq a/3$.

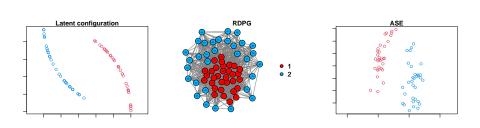

Then $\forall a \in (0,1)$, $\delta \in (0,1)$, $K \geq 2$, $\xi \leq a/3$, $\exists N(a,\delta,K,\xi) < \infty$ such that when $\min_k n_k \geq N$, with probability at least $1-\delta$,

- 1. Single linkage will produce perfect community detection.
- 2. Any ϵ -neighborhood graph will consist of at least K sub-graphs with no subgraph containing vertices from multiple communities.

This also holds for noisy points sampled from one-dimensional manifolds such that the manifolds are distance at least a apart.

Recovery from the Adjacency Matrix

Future Work

- 1. Show that the ASE of a random graph generated by these latent vectors produces the correct conditions for sufficiently large n.
- 2. Extend results to non-uniform distributions.
- 3. Extend results to multidimensional manifolds.
- 4. Relax condition for the minimum distance between manifolds.
- 5. Explore more robust clustering techniques for these latent configurations.
- 6. Extend results to the GRDPG.

Expectation Maximization for the PABM

Full data log-likelihood

$$\log L = \sum_{i < j} \sum_{k,l} z_{ik} z_{jl} (A_{ij} \log \lambda_{il} \lambda_{jk} + (1 - A_{ij}) \log(1 - \lambda_{il} \lambda_{jk}))$$
$$+ \sum_{i} \sum_{k} z_{ik} \log \pi_{k}$$

E-step

- $\gamma_{ik} = P(Z_i = k \mid \{\pi_l\}, \{\lambda_{jl}\})$
- $\log \gamma_{ik} \propto \log \pi_k + \sum_{j \neq i} \sum_l \pi_{jl} (A_{ij} \log \lambda_{il} \lambda_{jk} + (1 A_{ij}) \log(1 \lambda_{il} \lambda_{jk}))$

M-step

- $\pi_k = \frac{1}{n} \sum_i \gamma_{ik}$
- $\{\lambda_{ik}\} = \arg\max_{\{\lambda_{ik}\}} E_Z[\log L]$

MCMC Sampling for the PABM

Priors:

- $Z_i \stackrel{iid}{\sim} Categorical(\pi_1, ..., \pi_K)$
- $\lambda_{ik} \stackrel{ind}{\sim} Beta(a_{ik}, b_{ik})$

Full joint distribution:

$$\log p = constant$$

$$+ \sum_{i < j} \sum_{k} \sum_{l} z_{ik} z_{jl} (A_{ij} \log \lambda_{il} \lambda_{jk} + (1 - A_{ij}) \log(1 - \lambda_{il} \lambda_{jk}))$$

$$+ \sum_{k} \sum_{i} z_{ik} \log \pi_{k}$$

$$+ \sum_{i} \sum_{k} (a_{ik} - 1) \log \lambda_{ik} + (b_{ik} - 1) \log(1 - \lambda_{ik})$$

Variational Inference for the PABM

Mean Field Variational Inference

- Minimize $d_{KL}(p||q)$
 - ullet p is the joint distribution
 - ullet q is a density of some form
- Restrict $q(\vec{z}, \{\lambda_{ik}\}) = \Big(\prod_i q_{z_i}(z_i)\Big) \Big(\prod_{i,k} q_{\lambda_{ik}}(\lambda_{ik})\Big)$
- Iterative solution: $q_{\theta_i}^{(t+1)} \propto \exp(E_{\theta_{-i}^{(t)}}[\log p])$
- Approximate solution for the PABM
 - $Z_i \mid \{a'_{ik}\}, \{b'_{ik}\} \sim Categorical(\pi'_1, ..., \pi'_K)$
 - $\lambda_{ik} \mid \{a'_{-i,-k}\}, \{b'_{-i,-k}\}, \{\pi'_k\} \sim Beta(a'_{ik}, b'_{ik})$
 - Iteratively update $\{\pi_K'\}, \{a_{ik}'\}, \{b_{ik}'\}$ until convergence
